1 Einleitung

2 Architecture

2.1 Class structure

The project was separated into several classes. The given framework simple calls methods which are defined in the package at.jku.amp.lepatriinu.

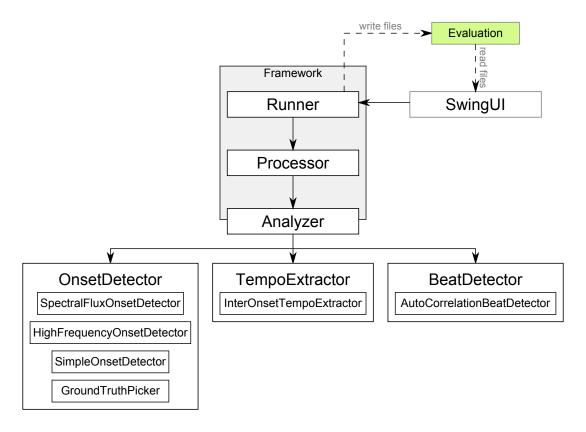

Figure 2.1: Class diagram

2.1.1 Analyzer

The *Analyzer* class defines all the constants that are needed for any algorithm in the project to succeed. In order to make central configurations possible, the constants are collected in this single class.

Furthermore it provides the central interface to the at.cp.jku.teaching.amprocessing project. It is initialized with a pre-processed (e.g. FFT) audio file of type Audiofile. The order of usage is important. In the first place, onset detection can be done. This information can directly be retrieved from the audio file. The found onsets are the base for tempo extraction. Therefore the onset list has to be provided as parameter of the tempo extraction function. Finally beat detection can be performed. In order to be able to use the best algorithms both the onset list as well as the calculated tempo should be provided.

- 1. Onset detection: onsets = performOnsetDetection()
- 2. Tempo extraction: tempo = performTempoExtraction(onsets)
- 3. Beat Detection: beats = performBeatDetection(onsets, tempo)

2.1.2 OnsetDetector

OnsetDetector is the abstract superclass of all onset detection algorithm's classes. It provides two different peak picking methods which can be used by any sub class.

- 1. The first peak picking method is taken from lecture slides (5.40) and called *Adaptive Thresholding*.
- 2. The second one is a slight modification of the adaptive thresholding algorithm. Instead of a threshold it simply isolates the highest magnitudes by zeroing everything but the peak as well as close neighbors that are lower. As a result a clear list of onsets remains. We called this method mountain climbing.

Constants

- USE_MOUNTAIN_PEAKPICK defines which peakpicking method to use. If constant is true, mountain peakpicking is chosen. Otherwise adaptive thresholding is performed.
- THRESHOLD_RANGE is used to specify the int size of the shifted slice used in adaptive thresholding as well as the range of zoroed neighbors in mountain climbing. The

best results were produced by a range of 5.

- PEAKPICK_USE_MEAN defines whether to use mean (true) or median (false) in order to select the threshold that is later on applied to all the onset calculations of adaptive thresholding.
- THRESHOLD is used to define a fixed int threshold for choosing the magnitude peaks when using mountain climbing. The value that prouced the best results in our experiments was 13.

2.1.4 BeatDetector

3 GUI

3.1 Purpose

As the pure command line interface provided too few possibilities to see the overall performance of our algorithms and lacks a simple way to execute batches of runs, we decided to develop a small GUI in Swing to match these two requirements.

3.2 Precaustionary Measures

In order to prevent the program from shutting down at any occurring error we had to edit the Runner a little bit and replace the System.exit(0) calls for simple runtime exceptions.

3.3 Structure

3.3.1 Files

Starting the program will allow you to select one or multiple files, which should be located in the "./data/" folder. On the bottom of the window three checkboxes let you choose, whether the output files should be generated. The "Run" buttons on the top are pretty self-explanatory.

3.3.2 Outputs

The outputs are displayed seperately for Onsets, Tempo and Beat, to keep a straight interface. Each of the three output tabs has the same layout:

• In the upper half, each output file will be displayed. For onsets and beat, only the respective "*.eval" files appear, whereas for the tempo the "*.bpms" as well as the "*.bpms.eval" file.

•	e bottom hal valuation.	f, the	selected	file	will	be	displaye	d as	well	as	the	sumn	nary	of
